## Problem Set 9 (Optional)

This problem set is not due; it is optional.

Reading: Chapter 34

---

**Problem 9-1.** Prove that the following problems are in  $NP$ :

- (a)  $D_1 = \{ \langle G, u, v, k \rangle \mid \text{there exists a simple path in } G \text{ between } u \text{ and } v, \text{ of length at least } k \}$
- (b)  $D_2 = \{ G \mid \text{it is possible to assign one of three "colors" to each vertex of } G \text{ such that no two neighboring vertices are assigned the same color} \}$

**Problem 9-2.** A *subgraph* of a graph  $G = (V, E)$  is a graph  $G' = (V', E \cap (V' \times V'))$  where  $V' \subseteq V$ ; i.e. it is a subset of the vertices together with all the edges of the original graph which are incident to these vertices.

Consider the problem **LARGESTCOMMONSUBGRAPH**: Given two graphs  $G_1$  and  $G_2$  and an integer  $k$ , determine whether there is a graph  $G$  with  $\geq k$  edges which is a subgraph of both  $G_1$  and  $G_2$ . (*Hint*: Reduce from **CLIQUE**.)

**Problem 9-3.** A *perfect matching* in an undirected graph  $G = (V, E)$  is a collection of edges  $E'$  such that each node has exactly one edge of  $E'$  incident to it. (In other words, the degree of each node in  $G' = (V, E')$  is exactly one.) Given a weight  $w(i, j)$  on each edge  $(i, j)$ , there is an  $O(n^3)$  algorithm to find a perfect matching in  $G$  of minimum total weight; you may use such an algorithm as a subroutine in your solution to the following problem, without worrying about how it works.

Give an algorithm for the traveling salesman problem with triangle inequality that produces a solution within a factor of  $3/2$  of the optimal one. (*Hint*: The key to the first algorithm given in class is to convert a minimum spanning tree to an Eulerian graph, and then shortcut that to obtain a tour; find a way to do this in a less expensive way by using matching.)

**Problem 9-4.** Here we will see how a *decision* algorithm for an  $NP$ -complete problem can be used to efficiently find a *witness* for that problem (and others).

- (a) Prove that if **CLIQUE**  $\in P$ , then there is a polynomial-time algorithm that takes a graph  $G$  and an integer  $k$  and finds a clique in  $G$  of size  $\leq k$  if one exists, and outputs "NONE" otherwise.
- (b) Under the same assumption (**CLIQUE**  $\in P$ ), prove that there is a polynomial-time algorithm that takes a set of  $n$  cities and the distances between them and finds a minimum length traveling salesman tour through all the cities.

**Problem 9-5.** Consider the following definition of a *randomized reduction*:

$A \leq_R B$  if there exists a polynomial time function  $f$  and a constant  $k$  such that

- $x \in A \Rightarrow \forall y \in \{0, 1\}^{|x|^k}, f(x, y) \in B$
- $x \notin A \Rightarrow \Pr[f(x, y) \in B] \leq 1/2$  (probability taken over choice of  $y \in \{0, 1\}^{|x|^k}$ )

(One way to interpret this definition is that  $y$  represents some random choices used in the reduction. That is, rather than letting  $f$  make random choices on its own, we give it a random string  $y$  to use for this purpose.)

Now, suppose  $A \leq_R B$ , where  $B \in P$  (i.e.,  $B$  has a poly-time algorithm). Describe a randomized (polynomial time) algorithm for  $A$  that is correct with probability at least  $1 - 1/2^{100}$ .
